

M5 calibration methodology — supervision signal on gaze-clean features

Both methods use the same 9 gaze-clean cursor approach features (hybrid xpath + linear-fallback extractor, 99.8% coverage). The only difference is the supervision signal: NB21 is trained on click labels and thresholded post-hoc; M5 is trained directly on NB22 gaze-regression labels. M5 is presented as a calibration methodology; AdSERP numbers are a reference point.
