

LHIPA paradox — does the regression-rate $\times$ LHIPA link survive controlling for trial duration?

Partial Spearman correlations (controlling for the third):
 $\rho(\text{regression_rate}, \text{mean_lhpa} \mid \text{duration}) = +0.135, p = 0.37$ (ns)
 $\rho(\text{duration}, \text{mean_lhpa} \mid \text{regression_rate}) = -0.862, p = 1.377\text{e-}14$ (***)
