

Examining behavior on AdSERP exhibits a forward-then-regressive structure.

(a) Examining a SERP — forward sweep with regressive returns

(b) Forward vs regressive — scroll-velocity asymmetry

forward sweep

- 62% of trials (1,686/2,701) have ≥ 1 regress-scan-regress cycle
multi-cycle scanning is the modal trial structure
- regression-episode tension: 1–3 ranks ($HWM < 8$) $\square$ 5–9 ranks ($HWM \geq 8$)
phase transition past $HWM \approx 8$ — local re-eval gives way to anchor return
- regressive scroll accelerates with depth; forward scroll is flat
asymmetry confirmed in mouse-events stream (rank-type-N/A)
